INTRODUCTION. What it takes to maintain our sense of equilibrium

"Simply standing in place requires contributions from our eyes, ears, brain, nerves, joints, ligaments, blood, and bones in a symphony of coordination. Take away one factor and the body can usually compensate. Take away two, and we may end up in a heap on the floor."

(1)

Here is how the actual process of balancing works.

1. Sensory systems figure out where the body is in space (chart below).

Feedback from sensory systems invloved in balancing

OCULAR FEEDBACK

Relative position of the line between the eye centers with respect to horizon is detected by the eyes

VESTIBULAR FEEDBACK

Relative position of the head with respect to gravity is monitored by the sensors deep in the inner ear

PROPRIOSEPTIVE FEEDBACK

Position of the body in space is monitored by sensors in muscles and joints

CUTANIOUS FEEDBACK

Pattern of pressure on the skin from the floor is detected by deep-pressure sensors in the skin

2. The brain processes the information and sends a signal to the muscles and joints to adjust their activity. The brain needs to process this information quickly. In some neurological disorders, this process fails, leading to balance problems.

3. Muscles and joints receive this information and make necessary modifications. They must be able to complete the assigned task, which requires a delicate dance between stability and flexibility.

The balancing reflex becomes quicker and more refined with practice.
